**Microstructural Effects in γ -Titanium Aluminides;
XD TiAl Alloys as an Example**

**L. Christodoulou
Department of Materials
Imperial College
London**

Influence of Reinforcement on Microstructure

- Refines the grain size
 - Grain structure uniformity
 - Improved workability
- Modifies kinetics of
 - Recrystallization
 - Grain growth
- TiB_2 does not appear to change intermetallic phase transformations or shift phase boundaries
- Complex precipitation reactions with nitrides, carbides and in matrices containing "active" transition elements

Microstructure Development in XD™TiAl

XDTM Processing Applied to TiAl-based Materials

- For gamma-based materials:
 - Investigated tens of reinforcement (borides, nitrides, carbides silicides) /matrix combinations
 - For compositions containing V, Cr, Mn, Fe, Co and Ni TiB_2 is the stable reinforcement
 - For compositions containing Zr, Nb, Mo, Hf, Ta and W the stable reinforcement is (Ti,X)B

Strengthening Contributions

Direct

Inherent strength of the matrix
Particulate

Indirect

Refinement of microstructure
Mechanical influences of elemental boron
in solid solution

$$* \sigma_c = \sigma_o + \Delta\sigma_{m,p} + \Delta\sigma_p$$

where σ_c = Strength of the composite

σ_o = Reference stress = strength of base alloy given identical thermal history

$\Delta\sigma_{m,p}$ = Strength increase of matrix due to presence of particulate (indirect effects)

$\Delta\sigma_p$ = Strength increase due to particulate (direct effect)

TiB₂ Reinforcement of XD™ Cast Titanium Aluminides

- Addition of TiB₂ results in strengthening of all titanium aluminide matrices examined
- The response to TiB₂ additions varies with base alloy composition

Direct Strengthening Contributions in XD™ Ti-Aluminides

Deformation controlled by strongest "barrier"

Ti-47Al + 50 v% TiB₂

• Correlation of strength to interparticle spacing maintained to high volume fractions of TiB₂ in Ti-47Al

Fracture Toughness as a Function of Microstructure

Ti-45Al-3V + 7 vol% TiB₂

Creep Trends

- Strong grain size dependence
- Lamellar microstructures superior to equiaxed
- Deformed lamellar particularly poor--"dynamic recrystallization" effectively results in very fine grain size and repeated stage I creep
- Reinforcements improve creep (all other microstructural features being equal)

Fracture Toughness as a Function of Microstructure

Ti-45Al-3V + 7 vol% TiB₂

TiB₂ Particle Stability under Service Conditions

Distribution of Particle Sizes by Equivalent Diameter
in Ti-43Al-2V + 7 vol% TiB₂

Average Particle
Equivalent Diameter = 1.78 μm
Standard Deviation = 0.98 μm

Average Particle
Equivalent Diameter = 1.85 μm
Standard Deviation = 1.15 μm

Types of properties investigated

- Vacancy properties
From recovery of irradiation-produced vacancies
- Atomic mobility
From kinetics of atomic order variations
atomistic mechanism: controlled by vacancy
concentration and vacancy migration
- High temperature deformation (creep)
Connected with dislocation climb:
directly controlled by self-diffusion,
i.e. atomic mobility

MATERIALS

1) High purity and commercial purity binary alloys,

prepared from high purity or commercial purity Ti and Al

Composition: $Ti_{1-x}Al_x$ with $x = 48-50-51.5-53-54.5-56$ at%

Processing route

Levitation melting and drop casting + remelting on cooled copper boat and directional solidification

Impurity determination in starting materials:

by activation analysis

Metallic impurities: neutron irradiation

Oxygen: charged particle (3He ions) irradiation

Metal	Impurity content (wt ppm)	
	Commercial Purity	High Purity
Titanium	Ti 40 (sponge) O = 2500 ± 200 typical: Fe = 100 to 1100 Si = 50 to 100	Ti VA31 (refined by iodide process) O = 27 Fe = 107 Zr = 95
Aluminium	Al6174 (double-electrolysis) Fe = 3.3 Mg = 17 Si = 120 Zn = 8	Al H3GS67 (zone refined) Total ≤ 1

2) Quaternary alloy: $Ti_{48}Al_{48}Nb_2Mn_2$ (CEASI), for creep tests

Processing route: plasma casting + melting on cooled copper boat and directional solidification.

MATERIALS CHARACTERIZATION

Chemical

Bulk concentrations

Determined by Atomic Emission Spectroscopy (ICP - AES)

In high-purity binary TiAl alloys: 50 - 56 at% Al:
bulk concentrations consistent with nominal composition
(deviations < 0.3 at%, usually 0.1 at%)

Homogeneity

Characterized by local X-ray emission (SEM - EDX)

- Al-rich binary TiAl alloys, 50 - 56 at% Al
(homogenized 24 h at 1125 °C)

Ti-56 at% Al is homogeneous
(instrumental standard deviation = 0.25 at%)

less Al-concentrated alloys: some residual heterogeneity
(standard deviation of concentration = 0.5 to 1.4 at%)

- Ti-48 at% Al alloys (high purity and commercial purity) and
Ti₄₈Al₄₈Nb₂Mn₂:

concentration fluctuations (after directional solidification)

in Ti₄₈Al₄₈Nb₂Mn₂:

Ti is fairly homogeneous

Al fluctuations of amplitude typically ≈ 2 at%

Nb and Mn: fluctuations anti-correlated to those of Al

MATERIALS CHARACTERIZATION

Structure

Methods:

Optical, SEM, TEM observations, X-Ray diffraction

Results

- Al-rich binary alloys 50-56 at% Al,
homogenized 24 h at 1125°C:
single phase γ , equiaxed grains
(in the Ti-50at%Al, presence of a very small amount of
 γ lamellae and α_2 particles)
- Ti-48at% Al (high purity and commercial purity),
Ti48-Al48-Nb2-Mn2
(after directional solidification)
 - large grains of lamellar $\gamma + \alpha_2$ structure, elongated in
the direction of solidification

1. VACANCY MIGRATION

Experimental

Materials: single-phase γ TiAl

Homogenized high purity alloys
composition: 50 to 54.5 at% Al

Production of point defects

low temperature (21 K) irradiation with 2.5 MeV electrons

Defect elimination

investigated by
residual electrical resistivity measurements,
during isochronal anneals
at increasing temperatures, in range 21 K - 800 K

1. Vacancy migration

Recovery of low-temperature electron-irradiated high-purity single-phase γ TiAl alloys

1. Vacancy migration

Results

2 main recovery stages, at ≈ 80 K and at ≈ 440 to 510 K

- Stage I assigned to close-pair recombination and
 self-interstitial migration
 position nearly independent of alloy composition
- Stage III assigned to vacancy migration
 (to be confirmed by positron lifetime
 measurements)
 shifted to higher temperature
 in alloys with higher Al content

Conclusion

Vacancy mobility **decreases**

when Al concentration **increases**

P

2. ATOMIC MOBILITY

Materials: single-phase γ TiAl

Homogenized high purity alloys
composition: 50 to 56 at% Al

Method

Analysis of atomic order changes resulting from heat treatments
(monitored by residual electrical resistivity measurements)

Qualitative data:
from isochronal annealing curves

Quantitative determination of characteristic parameters
(jump frequencies, activation enthalpies)
from kinetics of atomic order relaxation

Typical isochronal curve

Order changes during isochronal thermal treatments in TiAl intermetallic compounds

- Same behaviour as in Ni_3Al
- Reversible resistivity variations due to LRO changes

- Composition dependence:
 - amplitude of resistivity variations

- shift to lower temperatures of atomic mobility onset (T_0) with increasing Al content

- Atomic mobility becomes faster when deviating from stoichiometry

- At stoichiometry, atomic mobility is smaller than in Ni_3Al (shift by 60 K)

COMPOSITION DEPENDENCE OF ATOMIC MOBILITY AND VACANCY PROPERTIES

When **Al** concentration **increases**,

- Atomic mobility (i.e. atomic jump frequency: ν_{at})
increases
(consistent with results of Oikawa et al. (1992)
creep rate **increases** with **off-stoichiometry**)
- Vacancy mobility (i.e. vacancy jump frequency: ν_v)
decreases
- Consequently, vacancy concentration c_v appears
dependent on TiAl composition. Since
 $\nu_{at} \sim c_v \cdot \nu_v$,
 c_v **increases** with **increasing Al** content
(in agreement with vacancy formation enthalpy
calculations of Badura and Schaefer, 1993)

3. CREEP

Materials: two-phase Ti-48 at% Al alloys

High purity binary Ti-48 at% Al alloy

Commercial purity binary Ti-48 at% Al alloy

Quaternary Ti₄₈Al₄₈Nb₂Mn₂ alloy (CEASI)

Processed by melting on water-cooled copper boat and
directional solidification

Microstructure in all 3 alloys,
large elongated grains of lamellar $\gamma + \alpha_2$ structure

Creep tests at 800 °C
under high vacuum
compressive stress = 260 MPa

Results

Stationary creep

- in commercial binary and quaternary alloys,

creep rates are: similar
(consistent with results of Hayes and McQuay, 1994)

duration of stationary creep shorter in quaternary than
in commercial purity binary alloy
- in high purity binary alloy,
rate is one order of magnitude larger

Possible mechanism

Impurity (oxygen ?) strengthening of γ phase

Creep tests at 800 °C under high vacuum, compressive stress = 260 MPa

Two-phase Ti-48 at% Al alloys

Micro and Macro Segregation Patterns in a PACH Melted Near Gamma Titanium Aluminide

Objectives

To identify the physical and operational parameters which influence solute partitioning and macro-segregation in PACH melted titanium aluminides.

Plasma Melting Furnace PROCESS CONTROL

R&D Programme on Evaluation and Minimisation of Compositional Variations in PACH Melted Titanium Aluminides.

- Microstructural and SEM studies to determine the extent of variation in local solidification conditions and to ascertain the levels of micro-segregation.
- Development of quantitative chemical analysis procedures (GD-OES) for assessing the levels and the spatial variations in alloy composition across the ingot.
- Macrostructural and analytical studies to determine the correlations between process parameters, macrostructural development and macro-segregation.
- The development of process monitoring and control procedures to minimise periodic and / or random variations in melting and casting conditions.

Microstructural and SEM Studies

Objectives:

To determine the effects of process conditions on local solidification time and the extent of micro-segregation.

Experimental:

- Grain orientation measurements to determine the depth and shape of the melt pool and its variation with casting conditions.
- SDAS measurements to determine the extent of variation in local solidification time.
- Vertical float zoning to simulate the effects of different solidification rates on SDAS and solute partitioning.
- EDX studies to determine the effects of different solidification and casting conditions on micro-segregation.

Glow Discharge Optical Emission Spectrometry

Problems:

Assumes that the intensity of an element x of concentration C_x is linearly dependent on the emission yield k_x and the sputter rate q . Problems arise in that the sputter rate is matrix dependent and the emission yield is dependent on all three lamp parameters (voltage, current and argon flow rate). These parameters are not separately variable.

Experimental:

- Production of chemically homogeneous samples with varying alloy contents for the determination of calibration curves.
- Operational studies to determine voltage, current, flow rate correlation's and the effects on emission yield.
- Determination of sputter rate variations as a function of operating conditions and matrix composition.
- Determination of optimum operating conditions and calibration procedures.

Schematic illustration showing the layout and principal operating features of the LECO GDS Spectrat 750 Glow Discharge Optical Emission Spectrometer.

Crater depth measurement data showing possible correlations between sputter rate, excitation voltage and argon flow rate for Ti-Al based

GD-OES calibration curves for Aluminium in Titanium and Titanium / Aluminium alloys showing the effects of variations in Argon flow rate. Excitation voltage and lamp current were controlled so as to maintain a constant applied power of approximately 40 watts.

Macrostructural and Analytical Studies

Objectives:

To determine the effects process parameters, and in particular the role of transient variations in melting and casting conditions, on macrostructural development and macro-segregation in PACH melted Titanium Aluminide.

Operational Parameters:

- The frequency and rate of transfer of liquid metal between the hearth and the crucible.
- The height, trajectory and power of the crucible and hearth torches.
- The rate of delivery of the feedstock to the hearth.
- The rate of ingot withdrawal from the crucible and the extent of mould oscillation.
- The ingot top position and the level of liquid metal within the crucible.
- The extent of electro-magnetic stirring.

Effect of Ingot Withdrawal Rate on Melt Pool Depth and Al Concentration Variations in PACH Melted Ti-48Al-

Aluminium Concentration Variations in As-Cast and Isothermally Forged Ti-48Al-2Mn-2Nb

(a) 10 mm

Figure 13 Structure of Billet IF12 at End AA (Prior to Forging)

GD-OES Contour Map Showing Longitudinal Variations in Al Concentration as a Function of Distance From Dove-Tail (Ingot Bottom).

Transient changes in Al concentration and columnar grain orientation with distance from the dovetail.

Data acquisition data obtained for Bar 81 showing transient variations in ingot withdrawal conditions within the near-dovetail region (ingot bottom)

Parameters contributing to banding in PACH melted Ti-48Al-2Mn-2Nb:

- Inhomogeneous feed-stock.
- Intermittent pouring of liquid metal from the hearth to the crucible.
- Fluctuations in the height of liquid metal in the crucible.
- Variations in withdrawal rate.
- Changes in the height, pattern and power of the crucible and hearth torches.

Process Monitoring and Control

- Casting rate control through in process monitoring of the level of liquid metal in the crucible and the control of ingot withdrawal and the rate of delivery of the feed-stock to the hearth.
- Temperature distribution within the hearth and crucible through thermal imaging and the associated control of torch trajectories and operating parameters.
- Optimisation of stir coil design and operational parameters.

Structure of Control System

Bar 109 - 48-2-2, bar feedstock

Summary of GD-OES Results Showing Effect of Improved Process Control on Aluminium Concentration Variations and Levels of Macro-Segregation

Bar N°	Mean	Max	Min	Range	Std Dev	Comments
11	47.70	50.68	46.42	4.26	0.71	Withdrawal rate & torch current trials. (Compacts, no casting rate control)
16	47.99	49.86	44.70	5.16	0.72	Withdrawal rate & torch current trials. (Compacts, no casting rate control)
26	47.88	49.88	45.26	4.62	0.97	(Compacts, no casting rate control)
81	47.93	50.02	44.42	5.60	1.15	Cast start-up / dove-tail region. (Compacts, no casting rate control)
91	47.93	48.44	46.72	1.73	0.23	Torch current trials. (Bar stock, level detection & casting rate control)
11	48.45	50.52	45.17	5.36	1.09	EDX Micro-Segregation Data. (Inter-Dendritic)
N/A	47.81	51.16	45.28	5.88	0.83	Float Zoned (4.8 -15.0 mm/min). (Interdendritic)

Conclusions

- Despite partition coefficients close to unity ($C/C_0 \approx 0.94 - 1.05$) TiAl based alloys exhibit high levels of inter-dendritic segregation, primarily because of the high Al concentrations.
- GD-OES analysis has shown that these levels of segregation can occur on the macro scale and are often typified by the development of alternating bands of Al enrichment and depletion extending along the length of the ingot. These features are not detected using XRF analysis
- Macrosegregation patterns observed in cast TiAl ingots are retained after forging and have been linked to problems with cracking during forging and changes in heat treatment response during subsequent thermal processing.
- Macrosegregation is found to be most severe in ingots where transient variations in withdrawal rate are at a maximum.
